

# **MATGEOM LIBRARY USER MANUAL**

D. Legland

June 8, 2020

**Abstract** *The MatGeom library provides a collection of functions for geometric computing within the Matab environment. It is organised in several modules, devoted to generic computations in 2D or 3D, polylines and polygons operators, 3D meshes operators, or geometric graphs operators. Many plotting functions are provided to facilitate the graphical representation of computation results. The library is provided with a large amount of user help: code comments, function headers, demonstration scripts...*

# 1 Introduction

MatGeom is a library for geometric computing with Matlab in 2D and 3D. It contains several hundreds of functions for the creation and manipulation of 2D and 3D shapes such as point sets, lines, polygons, 3D meshes, ellipses...

The official homepage for the project is hosted on GitHub<sup>1</sup>. A starting help is provided in the [MatGeom wiki](#).

The library is organised into several modules:

**geom2d** General functions in euclidean plane

**polygons2d** Functions operating on point lists

**graphs** Manipulation of geometric graphs

**polynomialCurves2d** Representation of smooth polynomial curves

**geom3d** General functions in 3D euclidean space

**meshes3d** Manipulation of 3D polygonal meshes

---

<sup>1</sup><http://github.com/mattools/matGeom>

## 2 Module geom2d

The geom2d module of the MatGeom library allows to process geometric planar shapes such as point sets, edges, straight lines, bounding boxes, conics (circles and ellipses)... Most functions works for planar shapes, but some ones have been extended to 3D or to any dimension. Other modules provide additional functions for specific shapes: polygons2d, graphs, polynomialCurves2d.

## 2.1 Points and vectors

Both points and vectors are defined by their two cartesian coordinates, stored into a row vector of 2 elements:

```
1 pt = [x y];  
2 vect = [vx vy];
```

Point sets and vector sets are stored in a matrix with two columns, one for the x-coordinate, one for the y-coordinate:

```
1 pts = [x1 y1 ; x2 y2 ; x3 y3];  
2 vectList = [vx1 vy1 ; vx2 vy2 ; vx3 vy3];
```

### 2.1.1 Points

General functions operating on points.

#### **points2d**

Description of functions operating on points.

#### **midPoint**

Middle point of two points or of an edge.

#### **circumCenter**

Circumcenter of three points.

#### **isCounterClockwise**

Computes relative orientation of 3 points.

#### **polarPoint**

Creates a point from polar coordinates (rho + theta).

#### **angle2Points**

Computes horizontal angle between 2 points.

#### **angle3Points**

Computes oriented angle made by 3 points.

#### **distancePoints**

Computes distance between two points.

#### **transformPoint**

Applies an affine transform to a point or a point array.

#### **drawPoint**

Draws the point on the axis.

### 2.1.2 Point Sets

The following listings provides an overview of some functions operating on point sets. The result is shown on Figure 2.1.

```

1 % generate random data
2 rng(42); pts = randn([100 2]) * 15 + 50;
3 % compute derived shapes
4 centro = centroid(pts); bbox = boundingBox(pts);
5 elli = equivalentEllipse(pts); hull = convexHull(pts);
6 % display shapes
7 figure; hold on; axis([0 100 0 100]);
8 drawPoint(pts, 'color', 'k', 'marker', 'o', 'linewidth', 2);
9 drawPoint(centro, 'color', 'b', 'marker', '*', 'linewidth', 2, 'MarkerSize', 10);
10 drawBox(bbox, 'color', [0 0 .7], 'linewidth', 2);
11 drawEllipse(elli, 'color', [.7 0 0], 'linewidth', 2);
12 drawPolygon(hull, 'color', [0 .7 0], 'linewidth', 2);
13 legend({'Points', 'Centroid', 'BoundingBox', 'Equiv. Ellipse', 'Conv. Hull'}, 'Location', 'NorthEast');
```

**Figure 2.1:** Generation of a random point set and computation of geometric derived shapes.

#### clipPoints

Clips a set of points by a box.

#### centroid

Computes centroid (center of mass) of a set of points.

#### boundingBox

Bounding box of a set of points.

## 2.1 Points and vectors

### **principalAxes**

Principal axes of a set of ND points, returned as a centroid, a rotation matrix, and optionally a scaling factor. See also `EquivalentEllipse` and `EquivalentEllipsoid`.

### **angleSort**

Sorts points in the plane according to their angle to origin.

### **findClosestPoint**

Finds index of closest point in an array.

### **minDistancePoints**

Minimal distance between several points.

### **mergeClosePoints**

Merges points that are closer than a given distance.

### **hausdorffDistance**

Hausdorff distance between two point sets.

### **nndist**

Nearest-neighbor distances of each point in a set.

## 2.1.3 Vectors

General functions operating on vectors.

### **vectors2d**

Description of functions operating on plane vectors.

### **createVector**

Creates a vector from two points.

### **vectorNorm**

Computes norm of a vector, or of a set of vectors.

### **vectorAngle**

Angle of a vector, or between 2 vectors.

### **normalizeVector**

Normalizes a vector to have norm equal to 1.

### **isPerpendicular**

Checks orthogonality of two vectors.

### **isParallel**

Checks parallelism of two vectors.

### **transformVector**

Transforms a vector with an affine transform.

**rotateVector**

Rotates a vector by a given angle.

**2.1.4 Various drawing functions**

Some functions allow to draw less standard objects.

**drawVector**

Draws vector at a given position.

**drawArrow**

Draws an arrow on the current axis.

**drawLabels**

Draws labels at specified positions.

**drawShape**

Draws various types of shapes (circles, polygons...).

**2.2 Linear shapes**

Linear shapes encompass three kinds of shapes:

**straight lines** are infinite in each direction

**line segments, or edges** correspond to the set of points between two extremity points

**rays** emanate from a point, and are unbounded in one direction

**Figure 2.2:** Three examples of linear shapes: line segment, ray, and straight line. The ray and the line are clipped by the axis bounds.

An example of each of these three shapes is represented on Fig. 2.2.

## 2.2 Linear shapes

### 2.2.1 Straight lines

Straight lines are infinite in each direction.

#### **lines2d**

Description of functions operating on planar lines.

#### **createLine**

Creates a straight line from 2 points, or from other inputs.

#### **medianLine**

Creates a median line between two points.

#### **cartesianLine**

Creates a straight line from cartesian equation coefficients.

#### **orthogonalLine**

Creates a line orthogonal to another one through a point.

#### **parallelLine**

Creates a line parallel to another one.

#### **intersectLines**

Returns all intersection points of N lines in 2D.

#### **lineAngle**

Computes angle between two straight lines.

#### **linePosition**

Position of a point on a line.

#### **lineFit**

Fits a straight line to a set of points.

#### **clipLine**

Clips a line with a box.

#### **reverseLine**

Returns same line but with opposite orientation.

#### **transformLine**

Transforms a line with an affine transform.

#### **drawLine**

Draws a straight line clipped by the current axis.

### 2.2.2 Edges (line segments between 2 points)

Line segments correspond to the set of points between two extremity points. The term “edge” is used interchangeably with line segment.

## **edges2d**

Description of functions operating on planar edges.

## **createEdge**

Creates an edge between two points, or from a line.

## **edgeToLine**

Converts an edge to a straight line.

## **edgeAngle**

Returns the horizontal angle of edge.

## **edgeLength**

Returns the length of an edge.

## **parallelEdge**

Create a new edge parallel to another edge.

## **centeredEdgeToEdge**

Converts a centered edge to a two-points edge.

## **midPoint**

Middle point of two points or of an edge.

## **edgePosition**

Returns the position of a point on an edge.

## **clipEdge**

Clips an edge with a rectangular box.

## **reverseEdge**

Interverts the source and target vertices of edge.

## **intersectEdges**

Returns all intersections between two sets of edges.

## **intersectLineEdge**

Returns the intersection between a line and an edge.

## **transformEdge**

Transforms an edge with an affine transform.

## **edgeToPolyline**

Converts an edge to a polyline with a given number of segments.

## **drawEdge**

Draws an edge given by 2 points.

## **drawCenteredEdge**

Draws an edge centered on a point.

## 2.2 Linear shapes

### 2.2.3 Rays

Rays emanate from a point, and are unbounded in one direction.

#### **rays2d**

Description of functions operating on planar rays.

#### **createRay**

Creates a ray (half-line), from various inputs.

#### **bisector**

Returns the bisector of two lines, or 3 points.

#### **clipRay**

Clips a ray with a box.

#### **drawRay**

Draws a ray on the current axis.

### 2.2.4 Relations between points and lines

These functions determine relative position of a point (or an array of points) and a linear shape.

#### **distancePointEdge**

Minimum distance between a point and an edge.

#### **distancePointLine**

Minimum distance between a point and a line.

#### **projPointOnLine**

Projects of a point orthogonally onto a line.

#### **pointOnLine**

Creates a point on a line at a given position on the line.

#### **isPointOnLine**

Tests if a point belongs to a line.

#### **isPointOnEdge**

Tests if a point belongs to an edge.

#### **isPointOnRay**

Tests if a point belongs to a ray.

#### **isLeftOriented**

Tests if a point is on the left side of a line.

## 2.3 Smooth curves

Smooth curves comprises simple curves such as circles, ellipses, or other conics, as well as more generic curves such as Bezier curves.

### 2.3.1 Circles

Several function operate on circles. Circles are represented by a 1-by-3 array  $[xc \ yc \ r]$ , where  $xc$  and  $yc$  denote the circle center and  $r$  denotes the circle radius. Figure 2.3 presents the results of the computation obtained in the following script.

```

1 % construction of circum circle to three points
2 pA = [30 20]; pB = [80 40]; pC = [20 70];
3 circ = circumCircle(pA, pB, pC);
4 % polygon discretisation
5 poly = circleToPolygon(circ, 12);
6 % line-circle intersection
7 line = [60 70 5 2];
8 inters = intersectLineCircle(line, circ);

```

**Figure 2.3:** Construction of a circle from 3 points, discretization into a polygon, and computation of its intersection with a line.

#### **circles2d**

Description of functions operating on circles.

#### **createCircle**

Creates a circle from 2 or 3 points.

#### **createDirectedCircle**

Creates a directed circle.

## 2.3 Smooth curves

### **intersectCircles**

Computes the intersection points of two circles.

### **intersectLineCircle**

Compute the intersection point(s) of a line and a circle.

### **circleToPolygon**

Converts a circle into a series of points.

### **circleArcToPolyline**

Converts a circle arc into a series of points.

### **isPointInCircle**

Tests if a point is located inside a given circle.

### **isPointOnCircle**

Tests if a point is located on a given circle.

### **enclosingCircle**

Finds the minimum circle enclosing a set of points.

### **circumCircle**

Circumscribed circle of three points.

### **radicalAxis**

Computes the radical axis (or radical line) of 2 circles

### **drawCircle**

Draws a circle on the current axis.

### **drawCircleArc**

Draws a circle arc on the current axis.

## 2.3.2 Ellipses and Parabola

Ellipses are represented by a 1-by-5 array [xc yc a b theta], where xc and yc denote the ellipse center, a and b denote the lengths of the semi axes, and theta denotes the orientation of the first principal axis.

### **ellipses2d**

Description of functions operating on ellipses.

### **equivalentEllipse**

Computes the equivalent ellipse with same moments up to the second order as a set of points.

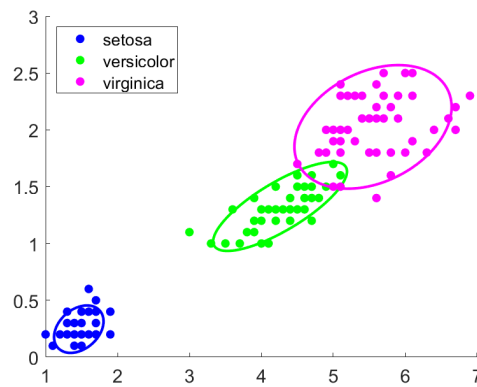

### **isPointInEllipse**

Checks if a point is located inside a given ellipse.

### **ellipsePerimeter**

Computes the perimeter of an ellipse.

**Figure 2.4:** Computation of equivalent ellipses to represent variance of groups within Fisher iris dataset.

### ellipseToPolygon

Converts an ellipse into a series of points.

### drawEllipse

Draws an ellipse on the current axis.

### drawEllipseArc

Draws an ellipse arc on the current axis.

### drawParabola

Draws a parabola on the current axis.

A small example for ellipses is given in following script.

```

1 load fisherIris;
2 figure; hold on; set(gca, 'fontsize', 14);
3 colors = {'b', 'g', 'm'};
4 hi = zeros(1, 3);
5 for i = 1:3
6     pts = meas((1:50)+(i-1) * 50, 3:4);
7     hi(i) = drawPoint(pts, 'Marker', 'o', 'Color', colors{i}, 'MarkerFaceColor', colors{i});
8     drawEllipse(equivalentEllipse(pts), 'Color', colors{i}, 'LineWidth', 2);
9 end
10 legend(hi, species([1 51 101]), 'Location', 'NorthWest');
```

## 2.3 Smooth curves

### 2.3.3 Splines

Spline curves are a convenient way to represent a large family of curves with a few number control points.

#### **cubicBezierToPolyline**

Computes an approximated polyline from Bezier curve control points, specifying the number of vertices.

#### **drawBezierCurve**

Draws a cubic bezier curve defined by 4 control points (Fig. 2.5).

**Figure 2.5:** *Bezier Curve through four points*

## 2.4 Polygonal shapes

This sections concerns simple polygons such as triangles, rectangles, and boxes. For polygons with an arbitrary number of vertices, see the Section 3.

### 2.4.1 Boxes

Boxes are used to represent bounds. They are represented by a four-element row vector containing the minimum and maximum coordinate along each dimension.

```
1 box = [xmin xmax ymin ymax];
```

#### **boxes2d**

Description of functions operating on bounding boxes.

#### **intersectBoxes**

Intersection of two bounding boxes.

#### **mergeBoxes**

Merges two boxes, by computing their greatest extent.

#### **randomPointInBox**

Generates random point within a box.

#### **boxToRect**

Converts box data to rectangle data.

#### **boxToPolygon**

Converts a bounding box to a square polygon.

#### **drawBox**

Draws a box defined by coordinate extents.

### 2.4.2 Triangles

Triangles are simply represented by a  $3 \times 2$  array of three points.

#### **isPointInTriangle**

Tests if a point is located inside a triangle.

#### **triangleArea**

Computes the signed area of a triangle.

### 2.4.3 Rectangles

A rectangle is represented by the coordinates of the upper-left vertex, and by the dimensions of the rectangle.

```
1 rect = [x0 y0 sizeX sizeY];
```

## 2.5 Transforms and angles

### **rectToPolygon**

Converts a rectangle into a polygon (set of vertices).

### **rectToBox**

Converts rectangle data to box data.

### **drawRect**

Draws rectangle on the current axis.

### **orientedBox**

Minimum-width oriented bounding box of a set of points.

### **orientedBoxToPolygon**

Converts an oriented box to a polygon (set of vertices).

### **drawOrientedBox**

Draws centered oriented rectangle.

## 2.5 Transforms and angles

### 2.5.1 Geometric transforms

The MatGeom library contains various functions for manipulation of geometric transforms. Most of them consider affine transforms in the plane, that can be represented by a 3-by-3 matrix in homogeneous coordinates:

$$\begin{pmatrix} x' \\ y' \\ 1 \end{pmatrix} = \begin{pmatrix} m_{xx} & m_{xy} & t_x \\ m_{yx} & m_{yy} & t_y \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} \quad (2.1)$$

where the  $m_{ij}$  correspond to the linear part of the transform (rotations, scaling, shear...) and the  $t_i$  correspond to the translation part. Note that in MatGeom, while points are represented as  $1 \times 2$  row vectors, the transform matrix is represented as in eq. 2.1.

### **transforms2d**

Description of functions operating on transforms.

### **createTranslation**

Creates the 3-by-3 matrix of a translation.

### **createRotation**

Creates the 3-by-3 matrix of a rotation by an angle  $\theta$ , corresponding to the following transform matrix:

$$R_\theta = \begin{pmatrix} \cos \theta & -\sin \theta & 0 \\ \sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Example:

```

1 >> createRotation(pi/6)
2 ans =
3     0.8660    -0.5000         0
4     0.5000     0.8660         0
5         0         0     1.0000

```

**createRotation90**

Matrix of a rotation around the origin by multiples of 90 degrees. Matrix values are therefore only 0 or  $\pm 1$ . Example:

```

1 >> createRotation90(1)
2 ans =
3     0    -1     0
4     1     0     0
5     0     0     1

```

**createScaling**

Creates the 3-by-3 matrix of a scaling in 2 dimensions.

$$R_{\theta} = \begin{pmatrix} s_x & 0 & 0 \\ 0 & s_y & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

**createHomothecy**

Creates the the 3-by-3 matrix of an homothetic transform.

**createBasisTransform**

Computes matrix for transforming a basis into another basis.

**createLineReflection**

Creates the the 3-by-3 matrix of a line reflection.

**fitAffineTransform2d**

Fits an affine transform using two point sets.

**registerICP**

Fits an affine transform by using Iterative Closest Point (ICP) algorithm.

**polynomialTransform2d**

Applies a polynomial transform to a set of points.

**fitPolynomialTransform2d**

Coefficients of polynomial transform between two point sets.

## 2.5.2 Angles

Angles are expressed in radians, counter-clockwise, with 0 corresponding to the horizontal direction. Many functions consider angles within the  $[0; 2\pi)$  domain.

## 2.6 Grids and tessellations

### **angles2d**

Description of functions for manipulating angles.

### **normalizeAngle**

Normalizes an angle value within the  $[0; 2\pi)$  domain.

### **angleAbsDiff**

Absolute difference between two angles.

### **angleDiff**

Difference between two angles.

## 2.6 Grids and tessellations

This sections presents functions used to generate less common geometric objects such as grids.

### **squareGrid**

Generates equally spaces points in plane.

### **hexagonalGrid**

Generates hexagonal grid of points in the plane.

### **triangleGrid**

Generates triangular grid of points in the plane.

### **crackPattern**

Creates a (bounded) crack pattern tessellation.

### **crackPattern2**

Creates a (bounded) crack pattern tessellation.

## 3 Module polygons2d

The **polygons2d** module contains functions operating on shapes composed of a vertex list, like polygons or polylines.

### Contents

---

<b>3.1 Data representation</b>	<b>24</b>
3.1.1 Definitions	24
3.1.2 Data structures	24
3.1.3 Parametrization	24

---

## 3.1 Data representation

### 3.1.1 Definitions

A **polyline** is the curve defined by a series of vertices. A polyline can be either **closed** or **open**, depending on whether the last vertex is connected to the first one or not. This can be given as an option in some functions in the module.

A **polygon** is the planar domain delimited by a closed polyline. We sometimes want to consider '**complex polygons**', whose boundary is composed of several disjoint domains. The domain enclosed by a single closed polyline is called '**simple polygon**'. Its boundary is called a '**linear ring**'.

We call **curve** a polyline with many vertices, such that the polyline can be considered as a discrete approximation of a "real" curve.

### 3.1.2 Data structures

A simple polygon or polyline is represented by a N-by-2 array, each row of the array representing the coordinates of a vertex. Simple polygons are assumed to be closed, so there is no need to repeat the first vertex at the end.

As both polygons and polylines can be represented by a list of vertex coordinates, some functions also consider the vertex list itself. Such functions are prefixed by 'pointSet'. Also, many functions prefixed by 'polygon' or 'polyline' works also on the other type of shape.

For multiple-connected polygons, the different connected boundaries are separated by a row [NaN NaN]. For some functions, the orientation of the polygon can be relevant: CCW stands for 'Counter-Clockwise' (positive orientation), CW stands for 'Clockwise'.

### 3.1.3 Parametrization

Polylines and polygons are parametrized in the following way:

- the  $i$ -th vertex is located at position  $i-1$
- points of the  $i$ -th edge have positions ranging linearly from  $i-1$  to  $i$

The parametrization domain for an open polyline is from 0 to  $N_v - 1$ , and from 0 to  $N_v$  for a closed polyline (in the latter case, positions 0 and  $N_v$  correspond to the same point).

Example:

```

1 % Simple polygon:
2 P1 = [1 1;2 1;2 2;1 2];
3 drawPolygon(P1);
4 axis([0 5 0 5]);
5 % Multiple polygon:
6 P2 = [10 10;40 10;40 40;10 40;NaN NaN;20 20;20 30;30 30;30 20];
7 figure; drawPolygon(P2); axis([0 50 0 50]);

```

## 3.2 Basic operations

### 3.2.1 Extracting sub-elements

These functions allow to extract specific elements or subsets of a polyline or a polygon.

**polygonLoops**

Divides a possibly self-intersecting polygon into a set of simple loops.

**polygonPoint**

Extracts a point from a polygon.

**polygonSubcurve**

Extracts a portion of a polygon.

**polygonEdges**

Returns the edges of a simple or multiple polygon.

**polygonVertices**

Extracts all vertices of a (multi-)polygon.

**polylinePoint**

Extracts a point from a polyline and a position.

**polylineSubcurve**

Extracts a portion of a polyline.

### 3.2.2 Measures

Some functions to compute area, perimeter, or more complex geometric measures on polygons.

**polygonBounds**

Computes the bounding box of a polygon.

**polylineLength**

Returns the length of a polyline given as a list of points.

**polygonLength**

Perimeter of a polygon.

**polylineCentroid**

Computes centroid of a curve defined by a series of points.

**polygonCentroid**

Computes the centroid (center of mass) of a polygon.

**polygonArea**

Computes the signed area of a polygon.

### 3.3 Smoothing and filtering

#### **polygonEquivalentEllipse**

Computes the ellipse with the same moments as the polygon.

#### **polygonSecondAreaMoments**

Computes second-order area moments of a polygon.

#### **polygonNormalAngle**

Computes the normal angle at a vertex of the polygon.

#### **polygonOuterNormal**

Outer normal vector for a given vertex(ices).

## 3.3 Smoothing and filtering

Simplification of a polygon or a polyline.

#### **resamplePolyline**

Distributes N points equally spaced on a polyline.

#### **resamplePolylineByLength**

Resamples a polyline with a fixed sampling step.

#### **resamplePolygon**

Distributes N points equally spaced on a polygon.

#### **resamplePolygonByLength**

Resamples a polygon with a fixed sampling step.

#### **densifyPolygon**

Adds several points on each edge of the polygon.

#### **smoothPolygon**

Smooths a polygon using local averaging.

#### **simplifyPolygon**

Simplifies a polygon by using Douglas-Peucker algorithm (([Douglas and Peucker, 1973](#))).

## 3.4 Global processing

More complex operations on polygons.

### **expandPolygon**

Expands a polygon by a given (signed) distance.

### **triangulatePolygon**

Computes a triangulation of the polygon.

### **polygonSkeletonGraph**

Computes the skeleton of a polygon with a dense distribution of vertices, using algorithm from [Ogniewicz and Kübler \(1995\)](#).

### **medialAxisConvex**

Computes the medial axis of a convex polygon (not fully functional).

### **polygonSymmetryAxis**

Tries to identify symmetry axis of polygon.

## 4 Module graphs

The aim of this module is to provide functions to easily create, modify and display geometric graphs (geometric in a sense the nodes are associated to geometric position in 2D or 3D).

### Contents

## 4.1 Data representation

The Graph module provides functionalities for the processing of geometric graphs. Graphs are defined by a set of nodes (or vertices), and a relation operator that defines which nodes are neighbors. Geometric graphs associate each node to a position, as a 2D or 3D point.

Graphs are represented by two variables:

**nodes** which contains coordinates of each vertex

**edges** which contains indices of start and end vertex.

These two information can be manipulated individually, or be fields of a structure.

Some graph functions consider adjacency list, as a cell array where each cell contains the indices of the neighbor vertices.

Others arrays may sometimes be used:

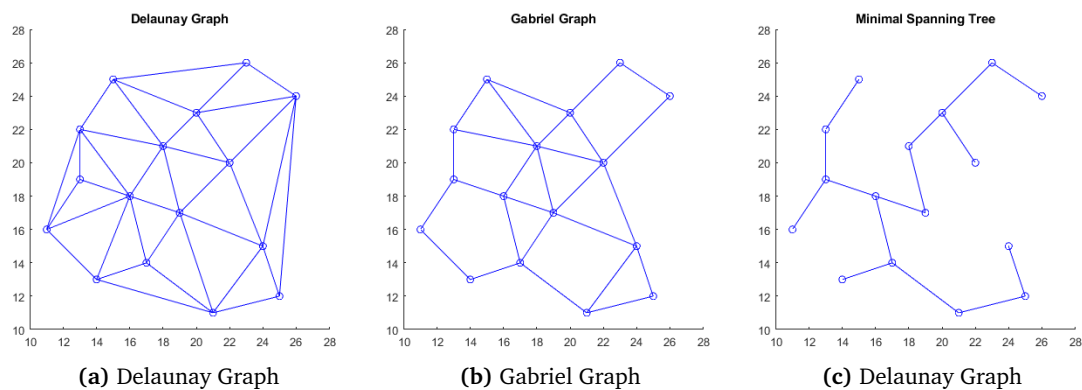

**faces** which contains indices of vertices of each face (either a double array, or a cell array)

**cells** which contains indices of faces of each cell.

## 4.2 Graph creation

### 4.2.1 Create graphs from point sets

The library contains several functions to generate classical graphs from a set of points. Some of them are illustrated on Figure 4.1.

**Figure 4.1:** Several graphs generated from a simple set of points.

### delaunayGraph

Graph associated to Delaunay triangulation<sup>1</sup> of input points (Fig. 4.1-a).

<sup>1</sup>[https://en.wikipedia.org/wiki/Delaunay\\_triangulation](https://en.wikipedia.org/wiki/Delaunay_triangulation)

## 4.2 Graph creation

### **euclideanMST**

Build the euclidean minimal spanning tree (MST) of a set of points. The minimal spanning tree is the graph with the smallest total length of edges that connect all the nodes of the graph (Fig. 4.1-c).

### **prim\_mst**

Computes the minimal spanning tree by using Prim's algorithm.

### **knnGraph**

Create the k-nearest neighbors graph of a set of points.

### **relativeNeighborhoodGraph**

Computes the Relative Neighborhood Graph (RNG) of a set of points. The RNG<sup>2</sup> connects two points by an edge whenever there does not exist any third point that is closer to candidate points than they are to each other.

### **gabrielGraph**

Computes the Gabriel Graph of a set of points. Gabriel Graph<sup>3</sup> connects points if the disc formed by the diameter of the two points does not contain any other point from the set (Fig. 4.1-b).

## 4.2.2 Voronoi Graphs

Voronoi diagrams are a fundamental data structure in geometry (Aurenhammer, 1991). Several functions are provided to generate graphs corresponding to Voronoi diagram of a set of points. In particular, Centroidal Voronoi Diagrams (CVD), or Centroidal Voronoi Tessellations (CVT), correspond to the case where the germs of the diagram are located on the centroids of the Voronoi polygons.

### **voronoi2d**

Computes a voronoi diagram as a graph structure.

### **boundedVoronoi2d**

Returns a bounded voronoi diagram as a graph structure.

### **centroidalVoronoi2d**

Centroidal Voronoi tessellation within a polygon.

### **centroidalVoronoi2d\_MC**

Centroidal Voronoi tessellation by Monte-Carlo.

### **boundedCentroidalVoronoi2d**

Create a 2D Centroidal Voronoi Tessellation in a box.

### **cvtUpdate**

Updates the germs of a CVT with given points.

---

<sup>2</sup>[https://en.wikipedia.org/wiki/Relative\\_neighborhood\\_graph](https://en.wikipedia.org/wiki/Relative_neighborhood_graph)

<sup>3</sup>[https://en.wikipedia.org/wiki/Gabriel\\_graph](https://en.wikipedia.org/wiki/Gabriel_graph)

### **cvtIterate**

Updates the germs of a CVT using random points with given density.

### 4.2.3 Create graph from images

Some functions allows to generate graphs from a (usually binary) 2D or 3D image. In most cases, node positions correspond to pixels or voxels of the original image.

#### **imageGraph**

Create equivalent graph of a binary image.

#### **boundaryGraph**

Get boundary of image as a graph.

#### **gcontour2d**

Creates contour graph of a 2D binary image.

#### **gcontour3d**

Create contour graph of a 3D binary image.

## 4.3 Operators on graphs

### 4.3.1 Graph processing (general applications)

#### **adjacencyListToEdges**

Convert an adjacency list to an edge array.

#### **pruneGraph**

Remove all edges with a terminal vertex.

#### **mergeGraphs**

Merge two graphs, by adding nodes, edges and faces lists.

#### **grMergeNodes**

Merge two (or more) nodes in a graph.

#### **grMergeMultipleNodes**

Simplify a graph by merging multiple nodes.

#### **grMergeMultipleEdges**

Remove all edges sharing the same extremities.

#### **grSimplifyBranches**

Replace branches of a graph by single edges.

### 4.3.2 Filtering operations on Graph

These functions adapt morphological operators to operate on graphs data structure. An array of values associated to the vertices must be provided to the functions. The new values are returned as result.

#### **grMean**

Compute mean from neighbours.

#### **grMedian**

Compute median from neighbours.

#### **grDilate**

Morphological dilation on graph.

#### **grErode**

Morphological erosion on graph.

#### **grClose**

Morphological closing on graph.

#### **grOpen**

Morphological opening on graph.

### 4.3.3 Geodesic and shortest path operations

**grShortestPath**

Find a shortest path between two nodes in the graph.

**grPropagateDistance**

Propagates distances from a vertex to other vertices.

**grVertexEccentricity**

Eccentricity of vertices in the graph.

**graphDiameter**

Diameter of a graph.

**graphPeripheralVertices**

Peripheral vertices of a graph.

**graphCenter**

Center of a graph.

**graphRadius**

Radius of a graph.

**grFindGeodesicPath**

Find a geodesic path between two nodes in the graph.

**grFindMaximalLengthPath**

Find a path that maximizes sum of edge weights.

### 4.3.4 Operations for geometric graphs

**grEdgeLengths**

Compute length of edges in a geometric graph.

**grMergeNodeClusters**

Merge cluster of connected nodes in a graph.

**grMergeNodesMedian**

Replace several nodes by their median coordinate.

**clipGraph**

Clip a graph with a rectangular area.

**clipGraphPolygon**

Clip a graph with a polygon.

**clipMesh2dPolygon**

Clip a planar mesh with a polygon.

### 4.3 Operators on graphs

#### **addSquareFace**

Add a (square) face defined from its vertices to a graph.

#### **grFaceToPolygon**

Compute the polygon corresponding to a graph face.

#### **graph2Contours**

Convert a graph to a set of contour curves.

### 4.3.5 Graph management (low level operations)

Some functions for removing elements from a graph by maintaining the consistency of the informations.

#### **grRemoveNode**

Remove a node in a graph.

#### **grRemoveNodes**

Remove several nodes in a graph.

#### **grRemoveEdge**

Remove an edge in a graph.

#### **grRemoveEdges**

Remove several edges from a graph.

## 4.4 Graph information

Several functions to obtain quantitative information about a graph.

### **grNodeDegree**

Degree of a node in a (undirected) graph.

### **grNodeInnerDegree**

Inner degree of a node in a graph.

### **grNodeOuterDegree**

Outer degree of a node in a graph.

### **grAdjacentNodes**

Find list of nodes adjacent to a given node.

### **grAdjacentEdges**

Find list of edges adjacent to a given node.

### **grOppositeNode**

Return opposite node in an edge.

### **grLabel**

Associate a label to each connected component of the graph.

## 4.5 Display

Display a graph, or specific elements of a graph.

### **drawGraph**

Draw a graph, given as a set of vertices and edges.

### **drawGraphEdges**

Draw edges of a graph.

### **fillGraphFaces**

Fill faces of a graph with specified color.

### **drawDigraph**

Draw a directed graph, given as a set of vertices and edges.

### **drawDirectedEdges**

Draw edges with arrow indicating direction.

### **drawEdgeLabels**

Draw values associated to graph edges.

### **drawNodeLabels**

Draw values associated to graph nodes.

## 4.6 Reading and writing graphs

### **drawSquareMesh**

Draw a 3D square mesh given as a graph.

### **patchGraph**

Transform 3D graph (mesh) into a patch handle.

## 4.6 Reading and writing graphs

Read and write graphs from text files using simple format.

### 4.6.1 Format

An example of graph is given in the following listing.

```
1 # graph
2 # nodes
3 5 2
4 10 10
5 20 10
6 10 20
7 20 20
8 27 15
9 # edges
10 6
11 1 2
12 1 3
13 2 4
14 2 5
15 3 4
16 4 5
```

Lines starting with a dash are comments. The first part of the file describes the nodes. It starts with a line containing the number of nodes, and the dimensionality of the graph (usually 2 or 3). Then the coordinates of the nodes follow.

The second part of the file describes the edges. It start with a line containing the number of edges. Then the index of source and target vertices of each edge follow. Vertex indices are 1-indexed.

### 4.6.2 Functions

#### **readGraph**

Read a graph from a text file.

#### **writeGraph**

Write a graph to an ascii file.

## 5 Module geom3d

The geom3d module allows to create, manipulate, transform, and visualize geometrical 3D primitives, such as points, lines, planes, polyhedra, circles and spheres.

## 5.1 Points and Vectors

Both points and vectors are represented by a 1-by-3 array of coordinates:

```
1 point = [x0 y0 z0];
2 vector = [dx dy dz];
```

Arrays of points or vectors are represented by N-by-3 arrays of coordinates.

### 5.1.1 Points

#### **midPoint3d**

Middle point of two 3D points or of a 3D edge.

#### **isCoplanar**

Tests input points for coplanarity in 3-space.

#### **transformPoint3d**

Transform a point with a 3D affine transform.

#### **distancePoints3d**

Computes euclidean distance between pairs of 3D Points.

#### **clipPoints3d**

Clips a set of points by a box or other 3d shapes.

#### **drawPoint3d**

Draws 3D point on the current axis.

### 5.1.2 3D Vectors

#### **transformVector3d**

Transform a vector with a 3D affine transform.

#### **normalizeVector3d**

Normalizes a 3D vector to have norm equal to 1.

#### **vectorNorm3d**

Norm of a 3D vector or of set of 3D vectors.

#### **hypot3**

Length of a 3D vector, or diagonal length of a cuboidal 3D box.

#### **crossProduct3d**

Vector cross product, faster than inbuilt MATLAB cross.

#### **vectorAngle3d**

Angle between two 3D vectors.

#### **isParallel3d**

Checks parallelism of two 3D vectors.

## 5.2 Linear shapes

### **isPerpendicular3d**

Checks orthogonality of two 3D vectors.

### **drawVector3d**

Draws vector at a given position.

### 5.1.3 Boxes

3D bounding boxes are used to determine physical extent of 3D geometries, or to clip geometries.

```
1 box = [xmin xmax ymin ymax zmin zmax];
```

## 5.2 Linear shapes

Linear shapes comprise straight lines, edges (line segments), and rays (half-lines).

A 3D Line is represented by a 3D point (its origin) and a 3D vector (its direction):

```
1 LINE = [X0 Y0 Z0 DX DY DZ];
```

A 3D ray is represented the same way as a line.

A 3D edge is represented by the coordinates of its extremities:

```
1 EDGE = [X1 Y1 Z1 X2 Y2 Z2];
```

### 5.2.1 Creation

#### **createLine3d**

Creates a line with various inputs.

#### **fitLine3d**

Fits a 3D line to a set of points.

#### **parallelLine3d**

Creates 3D line parallel to another one.

#### **transformLine3d**

Transforms a 3D line with a 3D affine transform.

#### **reverseLine3d**

Returns the same 3D line but with opposite orientation.

### 5.2.2 Relations with points

#### **distancePointLine3d**

Euclidean distance between 3D point and line.

**isPointOnLine3d**

Tests if a 3D point belongs to a 3D line.

**projPointOnLine3d**

Projects a 3D point orthogonally onto a 3D line.

**distancePointEdge3d**

Minimum distance between a 3D point and a 3D edge.

**linePosition3d**

Returns the position of a 3D point projected on a 3D line.

### 5.2.3 Clipping and conversion

This functions compute the intersection of a linear geometry with a 3D bounding box.

**clipLine3d**

Clips a line with a box and return an edge.

**clipEdge3d**

Clips a 3D edge with a cuboid box.

**clipRay3d**

Clip a 3D ray with a box and return a 3D edge.

### 5.2.4 Utility functions

**distanceLines3d**

Minimal distance between two 3D lines.

**edgeToLine3d**

Converts a 3D edge to a 3D straight line.

**midPoint3d**

Middle point of two 3D points or of a 3D edge.

### 5.2.5 Drawing

Drawing functions for linear geometries, performing clipping with the bounding box corresponding to the current figure axes.

**drawLine3d**

Draws a 3D line clipped by the current axes.

**drawEdge3d**

Draws 3D edge in the current axes.

**drawRay3d**

Draw a 3D ray on the current axis.

## 5.3 Planes

Planes are represented by a 3D point (the plane origin) and 2 direction vectors, which should not be colinear.

```
1 PLANE = [X0 Y0 Z0 DX1 DY1 DZ1 DX2 DY2 DZ2];
```

The plane origin and direction vectors can be accessed by using array indexing:

```
1 plane = ...
2 origin = plane(1,1:3);
3 v1 = plane(1, 4:6);
4 v2 = plane(1, 7:9);
```

### 5.3.1 Creation and transformations

#### **createPlane**

Creates a plane in parametrized form.

#### **medianPlane**

Creates a plane in the middle of 2 points.

#### **fitPlane**

Fits a 3D plane to a set of points.

#### **normalizePlane**

Normalizes parametric representation of a plane.

#### **parallelPlane**

Parallel to a plane through a point or at a given distance.

#### **reversePlane**

Returns the same 3D plane but with opposite orientation.

#### **transformPlane3d**

Transforms a 3D plane with a 3D affine transform.

### 5.3.2 Computing intersections

#### **intersectPlanes**

Returns the intersection line between 2 planes in space.

#### **intersectThreePlanes**

Returns the intersection point between 3 planes in space.

#### **intersectLinePlane**

Intersection point between a 3D line and a plane.

#### **intersectEdgePlane**

Returns intersection point between a plane and a edge.

**planesBisector**

Bisector plane between two other planes.

### 5.3.3 Point positions

**planePosition**

Computes the position of a point on a plane.

**planePoint**

Computes the 3D position of a point in a plane.

**projPointOnPlane**

Returns the orthogonal projection of a point on a plane.

**distancePointPlane**

Signed distance between 3D point and plane.

**isBelowPlane**

Tests whether a point is below or above a plane.

**projLineOnPlane**

Returns the orthogonal projection of a line on a plane.

### 5.3.4 Measures

**planeNormal**

Computes the normal to a plane.

**isPlane**

Checks if input is a plane.

**dihedralAngle**

Computes the dihedral angle between 2 planes.

### 5.3.5 Drawing

**drawPlane3d**

Draws a plane clipped by the current axes.

## 5.4 Polygons and polylines

These functions operate on 3D polygons and polylines that are not necessarily embedded into a plane. Both are represented by  $N \times 3$  array of vertex coordinates.

### 5.4.1 Computing intersections

#### **intersectLinePolygon3d**

Intersection point of a 3D line and a 3D polygon.

#### **intersectRayPolygon3d**

Intersection point of a 3D ray and a 3D polygon.

#### **clipConvexPolygon3dHP**

Clips a convex 3D polygon with Half-space.

### 5.4.2 Measurements

#### **polygonCentroid3d**

Centroid (or center of mass) of a polygon.

#### **polygonArea3d**

Area of a 3D polygon.

#### **polygon3dNormalAngle**

Normal angle at a vertex of the 3D polygon.

### 5.4.3 Drawing functions

#### **drawPolygon3d**

Draws a 3D polygon specified by a list of vertex coords.

#### **drawPolyline3d**

Draws a 3D polyline specified by a list of vertex coords.

#### **fillPolygon3d**

Fills a 3D polygon specified by a list of vertex coords.

### 5.4.4 3D Triangles

#### **triangleArea3d**

Area of a 3D triangle.

#### **distancePointTriangle3d**

Minimum distance between a 3D point and a 3D triangle.

#### **intersectLineTriangle3d**

Intersection point of a 3D line and a 3D triangle.

## 5.5 3D circles and ellipses

### **fitCircle3d**

Fits a 3D circle to a set of points.

### **circle3dPosition**

Returns the angular position of a point on a 3D circle.

### **circle3dPoint**

Coordinates of a point on a 3D circle from its position.

### **circle3dOrigin**

Returns the first point of a 3D circle.

### **drawCircle3d**

Draws a 3D circle.

### **drawCircleArc3d**

Draws a 3D circle arc.

### **drawEllipse3d**

Draws a 3D ellipse.

## 5.6 Spheres and smooth surfaces

### 5.6.1 Spheres

Spheres are defined by a center and a radius.

```
1 sphere = [x0 y0 z0 R]
```

#### 5.6.1.1 Creation and intersections

##### **createSphere**

Creates a sphere passing through 4 points.

##### **intersectLineSphere**

Returns the intersection points between a line and a sphere.

##### **intersectPlaneSphere**

Returns the intersection circle between a plane and a sphere.

#### 5.6.1.2 Drawing functions

Several functions are provided to draw spheres, or geometries defined over a sphere.

##### **drawSphere**

Draws a sphere as a mesh.

##### **drawSphericalEdge**

Draws an edge on the surface of a sphere.

##### **drawSphericalTriangle**

Draws a triangle on a sphere.

##### **fillSphericalTriangle**

Fills a triangle on a sphere.

##### **drawSphericalPolygon**

Draws a spherical polygon.

##### **fillSphericalPolygon**

Fills a spherical polygon.

##### **sphericalVoronoiDomain**

Computes a spherical voronoi domain.

### 5.6.2 Ellipsoids

Ellipsoids are a generalization of spheres, that are defined by a center, three radius, and three Euler angles (see Section 5.8.1).

```
1 Elli = [x0 y0 z0 RA RB RC PHI THETA PSI]
```

**equivalentEllipsoid**

Computes the ellipsoid with the same moments up to the second order as the given set of 3D points (Fig. 5.1). Note that it **does not** correspond to the inertia ellipsoid as defined with mechanical conventions.

**Figure 5.1:** Equivalent ellipsoid of a point cloud

**fitEllipse3d**

Fits a 3D ellipse to a set of points.

**ellipsoidSurfaceArea**

Computes an approximation of the surface area of an ellipsoid from the semi-axis lengths. The approximation formula is given by:

$$S \sim 4\pi \cdot \left( \frac{1}{3} (a^p \cdot b^p + a^p \cdot c^p + b^p \cdot c^p) \right)^{1/p}$$

with  $p = 1.6075$ . The resulting error should be less than 1.061%.

**oblateSurfaceArea**

Approximated surface area of an oblate ellipsoid.

**prolateSurfaceArea**

Approximated surface area of a prolate ellipsoid.

**drawEllipsoid**

Draws a 3D ellipsoid.

### 5.6.3 Cylinders

A cylinder is defined by two end-points and a radius. It is represented as a  $1 \times 7$  row vector (3 values for each endpoint, and 1 value for the radius).

## 5.6 Spheres and smooth surfaces

```
1 Cylinder = [X1 Y1 Z1 X2 Y2 Z2 R];
```

### **cylinderSurfaceArea**

Computes the surface area of a cylinder.

### **intersectLineCylinder**

Computes the intersection points between a line and a cylinder.

### **drawCylinder**

Draws a cylinder.

### **drawEllipseCylinder**

Draws a cylinder with ellipse cross-section.

## 5.6.4 Other smooth surfaces

*Figure 5.2: 3D revolution surface*

### **revolutionSurface**

Creates a surface of revolution from a planar curve.

### **surfaceCurvature**

Curvature on a surface from angle and principal curvatures.

### **drawTorus**

Draws a torus (3D ring).

### **drawSurfPatch**

Draws a 3D surface patch, with 2 parametrized surfaces.

## 5.7 3D Transforms

Transforms in 3D space are represented as 4-by-4 matrices in homogeneous coordinates:

$$\begin{pmatrix} x' \\ y' \\ z' \\ 1 \end{pmatrix} = \begin{pmatrix} m_{00} & m_{01} & m_{02} & m_{03} \\ m_{10} & m_{11} & m_{12} & m_{13} \\ m_{20} & m_{21} & m_{22} & m_{23} \\ 0 & 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} \quad (5.1)$$

### 5.7.1 Basic transforms

#### **createTranslation3d**

Creates the 4x4 matrix of a 3D translation.

$$T(\mathbf{u}) = \begin{bmatrix} 1 & 0 & 0 & u_x \\ 0 & 1 & 0 & u_y \\ 0 & 0 & 1 & u_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

#### **createScaling3d**

Creates the 4x4 matrix of a 3D scaling.

#### **createRotationOx**

Creates the 4x4 matrix of a 3D rotation around x-axis.

$$R_X(\theta) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \theta & -\sin \theta & 0 \\ 0 & \sin \theta & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

#### **createRotationOy**

Creates the 4x4 matrix of a 3D rotation around y-axis.

$$R_Y(\theta) = \begin{bmatrix} \cos \theta & 0 & \sin \theta & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \theta & 0 & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

#### **createRotationOz**

Creates the 4x4 matrix of a 3D rotation around z-axis.

$$R_Z(\theta) = \begin{bmatrix} \cos \theta & -\sin \theta & 0 & 0 \\ \sin \theta & \cos \theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

### 5.7.2 Euler Angles and basis transforms

#### **createBasisTransform3d**

Computes matrix for transforming a basis into another basis.

#### **eulerAnglesToRotation3d**

Converts 3D Euler angles to 3D rotation matrix.

#### **rotation3dToEulerAngles**

Extracts Euler angles from a rotation matrix.

#### **createRotation3dLineAngle**

Creates rotation around a line by an angle theta.

#### **rotation3dAxisAndAngle**

Determines axis and angle of a 3D rotation matrix.

#### **createRotationVector3d**

Calculates the rotation between two vectors.

#### **createRotationVectorPoint3d**

Calculates the rotation between two vectors.

### 5.7.3 Utility functions

#### **recenterTransform3d**

Changes the fixed point of an affine 3D transform.

#### **composeTransforms3d**

Concatenates several space transformations.

## 5.8 Angles and coordinate systems

### 5.8.1 3D Angles

Euler Angles are defined as follow:

- PHI is the azimuth, i.e. the angle of the projection on horizontal plane with the Ox axis, with value between 0 and 180 degrees.
- THETA is the latitude, i.e. the angle with the Oz axis, with value between -90 and +90 degrees.
- PSI is the 'roll', i.e. the rotation around the (PHI, THETA) direction, with value in degrees

*Figure 5.3: Definition of 3D angles.*

#### **anglePoints3d**

Computes angle between three 3D points.

#### **sphericalAngle**

Computes angle between points on the sphere.

#### **angleSort3d**

Sorts 3D coplanar points according to their angles in plane.

#### **randomAngle3d**

Returns a 3D angle uniformly distributed on unit sphere.

### 5.8.2 Coordinate transforms

#### **sph2cart2**

Converts spherical coordinates to cartesian coordinates.

## 5.9 Other drawing functions

### **cart2sph2**

Converts cartesian coordinates to spherical coordinates.

### **cart2sph2d**

Converts cartesian coordinates to spherical coordinates in degrees.

### **sph2cart2d**

Converts spherical coordinates to cartesian coordinates in degrees.

### **cart2cyl**

Converts cartesian to cylindrical coordinates.

### **cyl2cart**

Converts cylindrical to cartesian coordinates.

## 5.9 Other drawing functions

### **drawGrid3d**

Draws a 3D grid on the current axis.

### **drawAxis3d**

Draws a coordinate system and an origin.

### **drawAxisCube**

Draws a colored cube representing axis orientation.

### **drawCube**

Draws a 3D centered cube, eventually rotated.

### **drawCuboid**

Draws a 3D cuboid, eventually rotated.

## 6 Module meshes3d

The meshes3d module provides functions for the manipulation of 3D surface meshes. Meshes can be composed of triangular faces (“tri-mesh”), or have faces with variable number of vertices.

## 6.1 Mesh representation

A 3D surface mesh is represented by (at least) two arrays:

vertices	a $N_v \times 3$ array of double containing coordinates of the $N_v$ vertices
faces	an array containing the vertex indices for each face. For triangular meshes, faces are stored as a $N_f \times 3$ array. For generic meshes with faces with variable vertex number, faces is stored as a cell array, each cell containing the array of vertex indices for corresponding face.

Some functions may require or return additional data:

edges	an additional array that contains the source and target vertex of each edge
-------	---

## 6.2 Display functions

The library includes several functions to quickly display a mesh. Input arguments usually comprise `vertices` and `faces` arrays, but a mesh structure may sometimes be passed as well.

*Figure 6.1: Representation of a 3D polygonal mesh together with the face normals.*

### **drawMesh**

Draws a 3D mesh defined by vertex and face arrays (Fig. 6.1).

### **fillMeshFaces**

Fills the faces of a mesh with the specified colors.

### **drawFaceNormals**

Draws normal vector of each face in a mesh (Fig. 6.1).

## 6.3 Creation of meshes

The library contains many functions for generating polygonal meshes corresponding to classical polyhedra, such as platonic solids. It also provides facilities for converting from smooth surfaces.

### 6.3.1 Platonic solids

Several functions allows creation of meshes representing classical polyhedra. The results are typically of the form  $[v, f]$ , or  $[v, e, f]$ , where  $v$  is the array of vertex coordinates,  $f$  is the array of face vertex indices, and  $e$  is the array of edge vertex indices.

#### **createCube**

Creates a 3D mesh representing the unit cube (Fig. 6.2-a).

#### **createOctahedron**

Creates a 3D mesh representing an octahedron (Fig. 6.2-b).

*Figure 6.2: The five platonic solids and a soccer ball represented as 3D meshes.*

#### **createIcosahedron**

Creates a 3D mesh representing an Icosahedron (Fig. 6.2-c).

#### **createDodecahedron**

Creates a 3D mesh representing a dodecahedron (Fig. 6.2-d).

#### **createTetrahedron**

Creates a 3D mesh representing a tetrahedron (Fig. 6.2-e).

### 6.3.2 Other classical polyhedra

Other classical (non platonic) polyhedra can be easily generated.

### 6.3 Creation of meshes

#### **createSoccerBall**

Creates a 3D mesh representing a soccer ball (Fig. 6.2-f). It can be seen as a truncated icosahedron.

#### **createCubeOctahedron**

Creates a 3D mesh representing a cube-octahedron (Fig. 6.3-a).

#### **createTetrakaidecahedron**

Creates a 3D mesh representing a tetrakaidecahedron (Fig. 6.3-b). It can be seen as a truncated tetraedra.

#### **createRhombododecahedron**

Creates a 3D mesh representing a rhombododecahedron (Fig. 6.3-c). This mesh is composed of twelve identical faces, but vertices do not all have the same number of vertices.

#### **createStellatedMesh**

Replaces each face of a mesh by a pyramid.

#### **createDurerPolyhedron**

Creates a mesh corresponding to the polyhedron represented in Durer's "Melancholia" (Fig. 6.3-d).

**Figure 6.3:** Additional polyhedra that can be generated from the “meshes3d” module.

### 6.3.3 Conversion from smooth surface models

It is often convenient to convert a geometrical 3D model (cylinder, ellipsoid...) with known parameters into a discretized version represented by a mesh.

#### **cylinderMesh**

Creates a 3D mesh representing a cylinder.

#### **sphereMesh**

Creates a 3D mesh representing a sphere.

#### **ellipsoidMesh**

Converts a 3D ellipsoid to face-vertex mesh representation.

#### **torusMesh**

Creates a 3D mesh representing a torus.

#### **curveToMesh**

Creates a mesh surrounding a 3D curve (Fig. 6.4).

*Figure 6.4: Application of the curveToMesh function*

### 6.3.4 Other creation functions

#### **boxToMesh**

Converts a box into a quad mesh with the same size.

#### **surfToMesh**

Converts surface grids into face-vertex mesh.

#### **triangulateCurvePair**

Computes triangulation between a pair of 3D open curves.

#### **triangulatePolygonPair**

Computes triangulation between a pair of 3D closed curves.

#### **minConvexHull**

Returns the unique minimal convex hull of a set of 3D points. It consists in merging the triangular coplanar faces of the convex hull, resulting in a mesh composed of polygonal faces with various numbers of vertices.

#### **createMengerSponge**

Creates a cube with an inside cross removed. Can be used to test algorithms on meshes with complex topology.

#### **steinerPolytope**

Creates a steiner polytope from a set of vectors. Example (See Fig. 6.5):

```
1 vecList = [1 0 0; 0 1 0; 0 0 1; 1 1 1];  
2 [v, f] = steinerPolytope(vecList);  
3 figure; drawMesh(v, f);
```

**Figure 6.5:** Computation of the Steiner polytope obtained from four 3D vectors.

## 6.4 Operations on meshes

Most functions in this section transform a mesh into another mesh, or into another geometric data structure.

### 6.4.1 Filtering of meshes

Several functions allows for smoothing or simplifying meshes.

#### **smoothMesh**

Smoothes mesh by replacing each vertex by the average of its neighbors .

```
1 [V2, F2] = smoothMesh(V, F);
```

#### **meshVertexClustering**

Simplifies a mesh using vertex clustering.

```
1 [V2, F2] = meshVertexClustering(V, F, SPACING);
```

#### **concatenateMeshes**

Concatenates multiple meshes.

```
1 [V, F] = concatenateMeshes(V1, F1, V2, F2);
```

#### **splitMesh**

Returns the connected components of a mesh.

```
1 meshes = splitMesh(vertices, faces);
```

#### **subdivideMesh**

Subdivides each face of the mesh.

```
1 [v2, f2] = subdivideMesh(v, f, nDivs);
```

#### **triangulateFaces**

Converts face array to an array of triangular faces.

```
1 [v, f] = createCube;
2 f2 = triangulateFaces(f);
```

#### **mergeCoplanarFaces**

Merges coplanar faces of a polyhedral mesh.

```
1 [v2, f2] = mergeCoplanarFaces(v, f, tol);
```

#### **meshComplement**

Reverses the normal of each face in the mesh.

### 6.4.2 Intersection and clipping

Can identify and select elements of the mesh that intersect other primitives, or that are contained within a region.

#### **intersectLineMesh3d**

Intersection points of a 3D line with a mesh.

#### **intersectPlaneMesh**

Computes the polygons resulting from plane-mesh intersection.

#### **polyhedronSlice**

Intersects a convex polyhedron with a plane.

#### **clipMeshVertices**

Clips vertices of a surface mesh and remove outer faces.

#### **clipConvexPolyhedronHP**

Clips a convex polyhedron by a plane.

#### **cutMeshByPlane**

Cuts a mesh by a plane. Example:

```

1 % create triangulated mesh, and a plane from origin and normal vector
2 [v, f] = createSoccerBall; f = triangulateFaces(f);
3 plane = createPlane([-0.2 0 0], [-1 0 -1]);
4 % split the different parts of the mesh
5 [above, inside, below] = cutMeshByPlane(mesh, plane);
6 % draw the different parts
7 figure('color','w'); axis equal; hold on; view(3)
8 drawMesh(above, 'FaceColor', 'r'); drawMesh(inside, 'FaceColor', 'g'); drawMesh(below, 'FaceColor', 'b'
9 );
10 drawPlane3d(plane, 'FaceAlpha', .7)

```

**Figure 6.6:** Illustration of the “cutMeshByPlane” function.

### 6.4.3 Generic operations

#### **averageMesh**

Computes an average mesh from a list of meshes.

### 6.4.4 Cleanup meshes

Some functions for removing topological inconsistencies and trying to obtain a manifold mesh.

#### **trimMesh**

Reduces the memory footprint of a polygonal mesh by removing vertices that are not referenced by any face, and recomputing indices of remaining vertices.

#### **isManifoldMesh**

Checks whether the input mesh may be considered as manifold. A mesh is a manifold if all edges are connected to either two or one faces. Border edges should also form a 3D linear ring.

#### **ensureManifoldMesh**

Applies several simplification to obtain a manifold mesh.

#### **removeDuplicateFaces**

Removes duplicate faces in a face array.

#### **removeMeshEars**

Removes vertices that are connected to only one face.

#### **removeInvalidBorderFaces**

Removes faces whose edges are connected to 3, 3, and 1 faces.

#### **collapseEdgesWithManyFaces**

Removes mesh edges adjacent to more than two faces.

### 6.4.5 Mesh basic edition

Some low-level functions to modify a mesh.

#### **removeMeshVertices**

Removes vertices and associated faces from a mesh.

#### **mergeMeshVertices**

Merges two vertices and removes eventual degenerated faces.

#### **removeMeshFaces**

Removes faces from a mesh by face indices.

## 6.5 Measures on meshes

### 6.5.1 Query functions

Low level functions for investigating topology of meshes.

**meshFace**

Returns the vertex indices of a face in a mesh.

**meshFaceEdges**

Computes edge indices of each face.

**meshFaceNumber**

Returns the number of faces in this mesh.

**meshEdges**

Computes array of edge vertex indices from face array.

**meshEdgeFaces**

Computes index of faces adjacent to each edge of a mesh.

**trimeshEdgeFaces**

Computes index of faces adjacent to each edge of a triangular mesh.

**meshFaceAdjacency**

Computes adjacency list of face around each face.

**meshAdjacencyMatrix**

Computes the adjacency matrix of a mesh from set of faces.

**checkMeshAdjacentFaces**

Checks if adjacent faces of a mesh have similar orientation.

### 6.5.2 Geometric measures

Several functions allows to measure 3D intrinsic volumes, corresponding to volume, surface area, Euler number, or mean breadth (proportionnal to the integral of mean curvature along mesh). Some functions are dedicated to specific mesh types.

**meshSurfaceArea**

Surface area of a polyhedral mesh.

**trimeshSurfaceArea**

Surface area of a triangular mesh.

**meshFaceAreas**

Surface area of each face of a mesh.

**meshVolume**

Volume of the space enclosed by a polygonal mesh.

**meshEdgeLength**

Lengths of edges of a polygonal or polyhedral mesh.

**meshDihedralAngles**

Dihedral angle at edges of a polyhedral mesh.

**meshFacePolygons**

Returns the set of polygons that constitutes a mesh.

**polyhedronCentroid**

Computes the centroid of a 3D convex polyhedron.

**tetrahedronVolume**

Signed volume of a tetrahedron.

**polyhedronNormalAngle**

Computes the normal angle at a vertex of a 3D polyhedron.

**polyhedronMeanBreadth**

Mean breadth of a convex polyhedron.

**trimeshMeanBreadth**

Mean breadth of a triangular mesh.

### 6.5.3 Point positions

Describes the relative position of a 3D points with respect to the input mesh.

**isPointInMesh**

Checks if a point is inside a 3D mesh.

**distancePointMesh**

Shortest distance between a (3D) point and a triangle mesh.

## 6.6 Reading and writing meshes

The template of functions for reading (or writing) meshes is `readMesh_XXX` (or `writeMesh_XXX`), where XXX corresponds to the format used.

### 6.6.1 OFF format

**readMesh\_off**

Reads mesh data stored in OFF format.

**writeMesh\_off**

Writes a mesh into a text file in OFF format.

### 6.6.2 Polygon format

The “Polygon File Format”, or “Stanford triangle format”, is more general and more widely used than the OFF format. Partial support is provided by MatGeom.

#### **readMesh\_ply**

Reads mesh data stored in PLY (Stanford triangle) format.

#### **writeMesh\_ply**

Writes a mesh into a text file in PLY format.
